RESPONSE OF JAPANESE QUAIL TO FEED BY ORGANIC COMPOUNDS

M.A.A. Abdel-Mageed and E.M. EL-Kamash
Animal Prod. Res. Inst., Agric. Res. Center, Ministry of Agric, Doki, Giza, Egypt.

ABSTRACT:

The experiment was carried out at the Poultry Farm, Faculty of Agriculture, Fayoum University (middle Egypt). This study aims to show the effect of dietary malic acid (MA) supplementation as a growth promoter on Japanese quail performance, carcass characteristics, intestinal villi and pH, bacteria enumeration, some blood parameters and digestibility coefficients. A total number of 360 unsexed one day-old Japanese quail chicks (Coturnix coturnix japonica) were equally divided into four groups of six replicates each. Two starter-grower corn-soybean meal (C-SBM) basal diets were formulated to contain 24 % CP and 2900 kcal ME /kg diet and 22 % CP and 2750 kcal ME /kg diet, respectively. Also, two layer C-SBM basal diets were formulated to contain 20 % CP and 2900 kcal ME /kg diet and 18 % CP and 2750 kcal ME /kg diet, respectively. Each of the four basal diets was either unsupplemented or supplemented with 0.15% (1.5 kg/ton) dietary malic acid. Therefore, four experimental treatments were used in both starting-growing and laying periods. Each chick group fed one of the four experimental diets. At 35 days of age, a slaughter test was performed to determine carcass traits, edible giblets, lymphoid organs and intestinal villi, microflora count and pH. Blood samples were taken and assayed to determine some serum blood parameters. Digestibility trials were conducted to determine nutrients digestibility for starter-grower experimental diets. At laying period, egg number, weight, mass and production rate as well as feed intake and feed conversion were recorded. At the end of the 90-day period, egg samples were taken and broken out to determine internal egg quality and analysis. From nutritional of view, it was observed that using malic acid at a level of 0.15% (1.5 kg/ton) in Japanese quail diets containing sub-optimal energy and protein levels helped in reducing microflara count, particularly pathogens and in turn, improved quail performance and immunity. However, using MA at a level of 0.15% (1.5 kg/ton) in Japanese quail diets containing optimal energy and protein levels caused an increase in egg mass and a decrease in feed intake.

Key words: Malic acid, growth performance, carcass, villus height and width, bacteria enumeration and intestinal pH, blood serum, egg production, digestibility trials, egg quality, quail.

INTRODUCTION

Antibiotic growth promoters (AGP) in poultry diets have been banned for use due to the possibilities of antibiotic residue, the development of drug-resistant bacteria and a reduction in the ability to cure these bacterial diseases in humans **(Jensen, 1998)**. **Patten and Waldroup (1988)** reported that supplementing poultry diets with organic acids has become an important nutritional strategy to improve performance and health status of poultry fed diets devoid of AGP. Organic acids, as feed additives have received increasing attention as alternative AGP. It has made a tremendous contribution to the profitability in the intensive husbandry and providing people with healthy and nutritious poultry products. Livestock performance and feed efficiency are closely related with qualitative and quantitative microbial load of host animal including load in alimentary tract and environment **(Garrido et al., 2004)**. Malic acid (MA) is formed in metabolic cycles in the cells of plants and animals, including chickens and plays an important role in generating mitochondrial ATP both under aerobic and hypoxic conditions. Malic acid is not antibiotics but, if used correctly along with nutritional, managerial and biosecurity measures, it can be a powerful tool in maintaining the health of the gastrointestinal tract of poultry, thus improving their zootechnical performances **(Moharrery and Mahzonieh, 2005)**. Therefore, searching for alternative products that can be used in poultry feeds and aid in growth promotion, feed utilization improvement, and maintenance of gut health are taking place. Organic acids may stimulate endogenous enzymes, regulate gut microbial flora and help in maintaining animal's health. The key basic principle on the mode of action of organic acids on bacteria is that nondissociated (non-ionised, more lipophilic) organic acids can penetrate the bacteria cell wall and disrupt the normal physiology of certain types of bacteria **(Dhawale, 2005)**.

Malic acid (MA), an alpha-hydroxy organic acid, is a colorless, crystalline compound, COOH·CH2·CHOH·COOH, that occurs naturally in a wide variety of unripe fruit, including apples. It is sometimes referred to as a fruit acid. It is also formed in metabolic cycles in plant and animal cells, including chickens. Peripheral malate derives from feed sources and from synthesis in citric acid or Krebs cycle located in cells' mitochondria **(Lehninger, 1978 and Van Kol, 2005)**. Literature on dietary MA effect in poultry is limited and the evidence by which exogenous MA may affect quail performance is also limited. Therefore, the purpose of the current study was to evaluate the effects of dietary MA supplementation on Japanese quail performance, carcass characteristics, intestinal villi and pH, bacteria enumeration.

MATERIALS AND METHODS

The experiment was carried out at the Poultry Farm, Faculty of Agriculture, Fayoum University (middle Egypt). Three hundred and sixty

unsexed one day-old Japanese quail chicks were used in a 35 day growing trial. Chicks were individually wing-banded, weighed, and randomly distributed into four experimental groups of similar mean body weight (7.82±0.07 g/bird) of 90 birds each, which consists of six replicates of 15 birds each. At 35 days of age, birds were transferred to layer quail cages for a 90-day laying trial.

Management and experimental diets

Quail chicks were reared under similar management conditions. Ambient temperature was maintained at 34-36° C during the 1st week and weekly decreased by 2° C for the next three weeks. During the 5 th and 6 th week, temperature was maintained at 20-22° C. Birds daily received continuous artificial lighting during growing trial and 17 h afterwards. Chicks were fed the starter-grower diets from one to 35 day and the layer diets from 35 to 125 day of age. Mash feed and clean fresh tap water were provided ad liblitum.

Two starter-grower corn-soybean meal (C-SBM) basal diets were formulated, from the same batches of components, to contain 24 % CP and 2900 kcal ME /kg diet (HPHE-diet) and 22 % CP and 2750 kcal ME /kg diet (LPLE-diet). Also, two layer C-SBM diets were formulated to contain 20 % CP and 2900 kcal ME /kg diet and 18 % CP and 2750 kcal ME /kg diet. Each of the 4 basal diets was either unsupplemented or supplemented with 0.15% (1.5 kg/ton) MA. Therefore, four experimental treatments were used in both starting-growing and laying periods. Each chick group was fed one of the four experimental diets. The composition and calculated analysis of the experimental diets are shown in Table (1).

Measurements and collected data

Growth performance

Individual body weight (g) and feed intake (FI, g/bird) were weekly recorded to determine body weight gain (g), feed conversion ratio (g feed/g gain), protein conversion ratio and caloric conversion ratio. Mortality rate % was also calculated on a weekly basis.

Carcass parameters

At the end of the starting-growing period (35 days), 48 birds (six ♂ + six ♀/ treatment) used to determine carcass characteristics. BW nearly close to the mean were slaughtered to obtained the following criteria eviscerated carcass, dressing, breast and thigh weights. Abdominal fat was removed from gizzard and abdominal region and individually weighed for each carcass. Ovary-oviduct was carefully separated and accurately weighed. Edible giblets (liver, heart and gizzard) were individually separated and weighed. Lymphoid organs (thymus, bursa and spleen) were individually removed, weighed and calculated for each organ as % of live BW.

Villus height and width

Digesta from gastrointestinal tract were flushed at pH 7.4 to avoid damaging tissues. Intestinal samples of one cm in length were taken from the

middle of each segment of the duodenum, jejunum, and ileum. Samples were then fixed in 10 % buffered neutral formaldehyde solution, processed, and cut to 6-µm sections that were stained with hematoxylin and eosin and examined with a light microscope. A digital camera was used and villus height was measured from tip to villus bottom. Villus width was measured at villi bottom.

Bacteria enumeration and intestinal pH

At slaughter test performed using three samples of ileum content for each treatment were taken. Total microflora, colibacillus and lactobacillus of ileum content were enumerated. Lactobacilli/colibacillus ratio was also calculated. The pH of intestinal contents was directly determined by pH-meter.

Blood serum parameters

At the time of slaughter test, 48 blood samples (six ♂ and six ♀ / treatment) were taken and serum was separated by centrifugation for 10 minutes (3000 rpm) and stored in vials at -20^{o} C for later analysis. Frozen serum was thawed and assayed to determine, on individual bases, some biochemical parameters by using suitable commercial diagnostic kits and Atomic Absorption Spectrophotometer, following the same steps as described by manufactures. Colorimetric determination of serum total protein (TP, g/100 ml) was measured according to **Henry (1974)**. Albumin concentration (Alb, g/100 ml) was determined. Globulin concentration (Glo, g/100 ml) was calculated by the difference between TP and Alb, since the fibrinogen usually comprises a negligible fraction **(Sturkie, 1986)**. The Alb/Glo ratio was also calculated. Total lipids (TL, g/100 ml) and cholesterol (Cho, mg/100ml) were also determined.

Digestibility trials

A total number of 24 adult ♂ quail of six-weeks old were selected at the end of the growing trial and individually housed in metabolic cages for carrying out four digestibility trials (six ♂ /treatment) to determine the nutrient digestibility coefficient for dietary treatments in terms of crude protein (CP), crude fiber (CF), ether extract (EE) and nitrogen free extract (NFE) values. Digestibility trials lasted for seven days, a four-day preliminary period for adaptation to metabolic cages followed by a three-day main collection period in which FI was offered on an ad libitum daily basis and excreta output was quantitatively collected for each ♂ over three consecutive days.

Egg traits and quality

Eggs were daily collected and weighed. Averages of egg number (EN), egg weight (EW), egg mass (EM) and feed conversion ratio (FCR) were weekly calculated per each replicate for a 90-day laying period. Egg quality was assessed on five eggs collected per replicate during three days at the end of the 90-day period. Egg shape index (ESI) was determined according to **Stadleman (1977)**. Eggs were broken out and the liquid contents were put a side and shell plus membranes washed to remove adhering albumen. After drying, shell

weight % was measured. Shell thickness (STh) was measured by using a micrometer as an average of three points (top, medial and base). Egg analysis including albumin protein %, yolk protein %, ether extract % and cholesterol (mg /gm yolk) were performed according to **Washburn and Nix (1974)**.

Chemical and statistical analysis

Experimental diets and excreta were analyzed following procedures detailed by the Association of Official Analytical Chemists **(AOAC 1990)** for CP, CF, DM and EE. The NFE was calculated by the difference. Metabolizable energy (ME) of experimental diets was calculated considering the ME values of different feed ingredients **(NRC, 1994)**. Fecal nitrogen was determined according to **Jakobsen et al. (1960)**.

Obtained data were expressed as means ± standard error and statistically analyzed by analysis of variance (ANOVA) as a factorial arrangement of 2 x 2 according to **Steel and Torrie (1980)**. Also, the General Linear Model (GLM) procedure of **SPSS (1993)** computer statistical program was used. The significant means were ranked using Duncan's Range Test **(Duncan, 1955)**. Statistical significance level was tested at probability of $P \leq 0.05$.

RESULTS AND DISCUSSION

Growth performance

The results presented in Table (2) show the mean values of growth performance parameters in terms of body weight (BW), feed intake (FI), body weight gain (BWG), feed conversion ratio (FCR), protein conversion ratio, (PCR), caloric conversion ratio (CCR) and mortality rate (MR) %. Apart from MA, it was observed that feeding HPHE-diets resulted in significant increase in BW, BWG, FI, PI, CI, PCR and CCR values and significant decrease in MR % as compared to LPLE-diets. However, FCR was not significantly affected. Aside from diet type, feeding MA-supplemented diets gave significant improvement in BW, BWG, FCR, PCR and CCR as well as significant decrease in FI and MR % in comparison to MA-free diets. However, both PI and CI were not significantly affected. Supplementing MA to HPHE-diet had no significant effect on BW, BWG, FCR, PI, CI, PCR and CCR, whereas it significantly decreased FI and MR % as compared to the corresponding control diet. However, supplementing MA to LPLE-diet significantly improved BW, BWG, FCR, PCR and CCR significantly decreased FI and MR %, but it had no significant effect on PI and CI.

These results are in agreement with those showed that organic acids have positive effects on poultry growth **(Chaveerach et al., 2004)** and FI was decreased with increasing dietary propionic acid levels **(Cave, 1984).** The improvement in FC may be due to the acidic conditions that make the nutrients more available **(Boling et al., 2001)** which monitors better performance. Oppositely, other results have shown that adding MA in drinking water did not show significant difference in BW **(Moharrery and Mahzonieh, 2005)** and

BW was not significantly affected by organic acid treatments **(Denli et al., 2003).**

Carcass characteristics

Information found in Table (3) indicate that birds given HPHE-diet had significantly higher eviscerated carcass %, dressing %, breast % and ovary-oviduct % but significantly decreased abdominal fat % as compared to those fed LPLE-diet regardless of MA. Irrespective of diet type, no significant influence was found due to MA supplementation on carcass parameters except for abdominal fat % that was significantly decreased and ovary-oviduct % that was significantly increased. Adding MA to HPHE-diet had no significant influence on eviscerated carcass %, dressing %, breast %, abdominal fat % and ovary-oviduct % as compared to the corresponding MA- free diet. However, supplementing MA to LPLE-diet had significantly increased eviscerated carcass %, dressing %, breast % and ovary-oviduct %. However, abdominal fat % was significantly decreased as compared to the corresponding MA- free diet.

Edible giblets and lymphoid organs

Data in Table (4) indicated that regardless of MA, feeding HPHE-diet had significantly higher liver % and heart %. However, gizzard % was not significantly affected as compared to LPLE-diet**.** Regardless of diet type, MA supplementation caused no significant effect on edible giblets. Supplementing MA to HPHE- or LPLE-diets had no effect on edible giblets as compared to the corresponding MA-free diet. Concerning lymphoid organs results, it was noticed that neither diet type nor MA showed significant effect, except for thymus gland that was significantly increased by MA supplementation. Adding MA to HPHE- or LPLE-diets caused a significant increase in lymphoid organs % as compared to the corresponding MA-free diet.

The present results are in agreement with those have shown that liver % was not significantly affected by MA **(Moharrery and Mahzonieh, 2005)** and organic acids (**Denli et al. 2003)**. It can be seem that thymus is a good indicator of immune function. **Shelat et al. (1997)** revealed that thymus size is a sensitive indicator of health and acute or chronic stress response.

Villus height and width

The mean values of intestinal villus height and width are summarized in Table (5). Apart from MA, diet type caused no significant effect on villus height and width in different intestinal segments. Irrespective of diet type, MA supplemented-diets had significantly increased intestinal villus height and width in different intestinal segments as compared to MA-free diets. Supplementing MA to HPHE- or LPLE-diets had significantly increased intestinal villus height and width in different intestinal segments as compared to the corresponding MA-free diets.

Bacteria enumeration and intestinal pH

The mean values of total microflora count, lactobacillus, colibacillus and lactobacillus/colibacillus ratio of the ileum content as well as intestinal pH are given in Table (6). Regardless of MA, diet type caused no significant effect on total microflora count, colibacillus and lactobacillus and lactobacillus/colibacillus ratio of the ileum content as well as intestinal pH. Irrespective of diet type, MA supplementation resulted in significant decrease in total microflora count, colibacillus count and intestinal pH as well as significant increase in lactobacillus count, lactobacillus/colibacillus ratio as compared to MA-free diets. Supplementing MA to HPHE- or LPLE-diets resulted in significant decrease in total microflora count, colibacillus count and intestinal pH as well as significant increase in lactobacillus count, lactobacillus/colibacillus ratio as compared to the corresponding MA-free diets.

These results are in agreement with those of **Moharrery and Mahzonieh, (2005)** who found that E. coli count was significantly decreased by MA. This was due to organic acids that can inhibit growth of many bacteria and toxin-producing molds **(Roy, 2002)**. Intestinal pH was not affected by formic and propionic acids **(Thompson and Hinton, 1997).** The acidic pH allows establishment of microorganisms, particularly Lactobacillus spp. **(Sarra et al., 1985)** and prevents E. coli growth and these conditions make the absorptive area more beneficial **(Dofing and Gottschal, 1997).**

Blood serum parameters

Results concerning total protein (TP), albumin (Alb), globulin (Glo), Alb/Glo ratio, total lipids (TL) and cholesterol (Cho) are shown in Table (7). There were no significant differences in either TP or Cho among different treatments. Irrespective of MA, HPHE-diet caused significant increase in Alb and Alb/Glo ratio and significant decrease in Glo and TL. Regardless of diet type, MA supplementation resulted in no significant differences among all studied traits. Supplementing MA to HPHE-diet had similar Alb, Glo, Alb/Glo ratio and TL values to those of the corresponding MA-free diet. The same trend was observed in case of supplementing MA to LPLE-diet.

Nutrients digestibility coefficients

Data regarding digestibility coefficients of crude protein (CP), crude fiber (CF), ether extract (EE) and nitrogen free extract (NFE) values for experimental starter-grower diets are given in Table (8). There were no significant differences in CF and NFE digestibilities among different treatments. Apart from MA, HPHE-diet caused significant increase in CP and EE digestibility as compared to LPLE-diet. Away from diet type, MA supplementation caused significant increase for only CP digestibility. Supplementing MA to HPHE-diet had similar CP and EE digestibility as compared to the corresponding MA-free diet. However, supplementing MA to LPLE-diet caused a significant increase in CP and similar EE digestibility as

compared to the corresponding MA-free diet In general, the improvement due to adding MA may be attributed to improving intestinal microbial balance. In other words, MA helps to keep the intestinal tract healthy and when the epithelial tissue is healthy, there is improve and better absorption of all nutrients **(Kaistha et al., 1996).**

Egg analysis

Results concerning egg analysis in terms of albumin protein (Albp) %, yolk protein (Yp) %, yolk ether extract (YEE) % and yolk cholesterol (YCho) are shown in Table (9). Regardless of MA, HPHE-diet caused significant increase in Yp % and significant decrease in YEE % and YCho %. These results are in agreement with previous studies of **Andersson (1979)**; **Akbar et al. (1983)** and **Garcia et al. (2005)** who reported that Yp contents increased with higher dietary CP levels. Irrespective of diet type, MA supplementation caused significant decrease in YCho %. Supplementing MA to HPHE-diet caused similar Yp % and YEE % as well as significant decrease in YCho % as compared to the corresponding MA-free diet. The same trend was observed in case of supplementing MA to LPLE-diet.

Egg quality

Data regarding egg quality in terms of shell thickness (STh), egg shape index (ESI), egg specific gravity (ESG), albumin weight (Alb) %, shell weight (S) % and yolk weight (Y) % are presented in Table (10). There were no significant differences in SG, Y % and Alb % among different treatments. These results are in a relative harmony with the results of **Garcia et al. (2005)** who reported that dietary CP levels had no effect on Y %. On the contrary, increasing CP level increased Y % and reduced Alb % **(Akbar et al., 1983),** increased Y % **(Yakout et al., 2004)** and decreased Y % **(Zanaty, 2006)**. Regardless of MA, HPHE-diet caused significant increase in STh, ESI and S %. Similar observations have been reported by **Yakout et al. (2004)** and **Zanaty (2006)** who found that STh was significantly increased with increasing CP. This may be due to the increase in EW or the enhancing of Ca deposition in the shell matrix. Irrespective of diet type, MA supplementation caused significant increase in STh, ESI and S %. Supplementing MA to HPHE-diet had similar ESI, STh and S % to those of the corresponding MA-free diet. However, supplementing MA to LPLE-diet caused significant increase in ESI, STh and S % as compared to the corresponding MA-free diet. **Laying performance**

Results concerning laying performance in terms of egg production (EP) %, egg number (EN), egg weight (EW), egg mass (EM), feed intake (FI) and feed conversion ratio (FCR) values are shown in Table (11). Irrespective of MA, HPHE-diet caused significant improvements in EP %, EN, EW, EM and FCR as well as significant decrease in FI as compared to LPLE-diet. These results are in harmony with those of **Abdel-Rahman (1993)**; **Shrivastav et al., (1993); Zanaty et al. (2001); Yakout et al. (2004)** and **Garcia et al. (2005)**

who reported that EP, EW, EM and FCR were improved with increasing dietary CP level. However, **Garcia et al., (2005)** reported that FI was not significantly affected by dietary CP level. Regardless of diet type, MA supplementation caused significant improvements in EP % and FCR as well as a significant decrease in FI. Supplementing MA to HPHE-diet had similar EP %, EN, EW, EM and FCR to the corresponding MA-free diet. The only exception, FI was significantly decreased as compared to the corresponding MA-free diet. On the other hand, supplementing MA to LPLE-diet caused significant improvements in EP %, EW, EM and FCR except for FI that was significantly decreased as compared to the MA-free diet.

From nutritional point of view, it could be concluded that using MA at a level of 0.15 % in Japanese quail diets containing sub-optimal energy and protein levels helped in reducing microflara count, particularly pathogens and in turn, improving quail performance and immunity. However, using MA at a level of 0.15 % in Japanese quail diets containing optimal energy and protein levels caused an increase in EM and a decrease in FI.

Table (1): Composition and calculated analysis of the experimental starter-grower and layer basal diets.

Ingredients	Percentage (%)

استجابة السمان اليابانى للتغذية بالمركبات العضوية

محمد أحمد على عبد المجيد وعزت موسى عبد التواب القماش
معهد بحوث الإنتاج الحيواني - الدقي - جيزة - مصر.

نفذت هذه التجربة فى مزرعة كلية الزراعة جامعة الفيوم تم أستخدم ٣٦٠ كتكوت سمان يابانى غير مجنس عمر يوم تم توزيعها بالتساوى على ٤ معاملات غذائية (٦ مكررات/معاملة) استمرت حتى عمر ٢٠ أسبوع وذلك بهدف معرفة تأثير إضافة حمض الماليك على أداء النمو وبعض صفات الذبيحة ومقاييس الدم وكذلك أداء إنتاج البيض للسمان اليابانى.

تم تكوين عليقتين نمو (كنترول) **الأولى** تحتوى على ٢٤٪ بروتين خام و٢٩٠٠ كيلو كالورى طاقة ممثلة/كجم علف لتغطى الاحتياجات الغذائية للسمان اليابانى طبقاً للمجلس القومى الأمريكى للبحوث لسنة ١٩٩٤ **والثانية** تحتوى على ٢٢٪ بروتين خام و٢٧٥٠ كيلو كالورى طاقة ممثلة/كجم علف لتغذية الكتاكيت خلال فترة النمو (١- ٣٥ يوم). تم تكوين عليقتين بياض (كنترول) **الأولى** تحتوى على ٢٠٪ بروتين خام و٢٩٠٠ كيلو كالورى طاقة ممثلة/كجم علف لتغطى الاحتياجات الغذائية للسمان اليابانى طبقاً للمجلس القومى الأمريكى للبحوث لسنة ١٩٩٤ **والثانية** تحتوى على ١٨٪ بروتين خام و٢٧٥٠ كيلو كالورى طاقة ممثلة/كجم علف وذلك لتغذية الطيور خلال فترة إنتاج البيض (٦-٢٠ أسبوع). تم إضافة أو عدم إضافة ١.٥كجم/طن علف حمض الماليك إلى علائق النمو والبياض الكنترول، وبذلك يكون هناك ٤ معاملات غذائية فى كل من فترة النمو وإنتاج البيض.

فى نهاية فترة النمو (عمر ٣٥ يوم) تم ذبح ١٢ طائر (٦ إناث+٦ ذكور/معاملة) من كل معاملة (أنثى+ ذكر/مكرر) لتقدير صفات الذبيحة. كما تم جمع ١٢ عينة دم من طيور كل معاملة وقت الذبح لتقدير بعض مكونات سيرم الدم كما تم ايضا اجراء تجربة هضم فى نهاية فترة النمو لتقدير معاملات هضم المركبات الغذائية باستخدام ٦ ديوك من كل معاملة. وفى فترة إنتاج البيض (٧-١٩ أسبوع) تم تسجيل عدد ووزن وكتلة البيض ومعدل إنتاج البيض والغذاء المأكول ومعدل تحويل الغذاء، كما تم تكسير عدد ١٠ بيضات من كل معاملة فى نهاية فترة الـ ٩٠ يوم من إنتاج البيض لتقدير جودة البيض وكذلك التحليل الكيماوى للبيض.

أوضحت النتائج خلال فترة النمو أن إضافة حمض الماليك بمعدل ١.٥ % للعليقة المحتوية على مستوى البروتين والطاقة طبقاً للـ NRC أدى الى تقليل اعداد الكائنات الحية الدقيقة الضارة الموجودة بأمعاء الطيور مما ادى الى تحسين اداء ومناعة الطيور. بينما وجد ان اضافة حمض الماليك بمعدل ١.٥ % للعليقة المحتوية على مستوى البروتين والطاقة طبقاً للـ NRC أدى الى زيادة كتلة البيض وتحسن كلا من معظم صفات إنتاج البيض ، دليل شكل البيضة ، سمك القشرة ، نسبة الصفار ، ونسبة القشرة. وتقليل العلف الماكول مما يودى الى تحسين القيمة الاقتصادية.

الكلمات الدالة: (حمض الماليك –أداء – سيرم الدم - إنتاج البيض– جودة البيضة – هضم - السمان).
